

Brain Tumor Analysis Report

Patient Name: Morgan

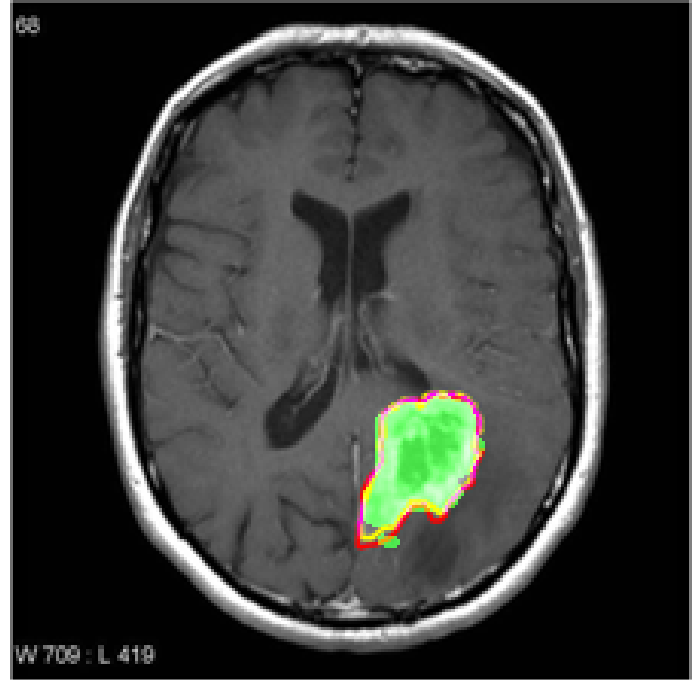

Age: 35

Gender: Male

Imaging Results

Original MRI Image

Segmented Tumor (Overlay)

AI-Generated Analysis

1. FINDINGS:

- Location: The lesion is located in the left temporo-parietal region, appearing intraparenchymal with irregular periventricular extension.
- Size & Shape: The estimated tumor volume is 6.23 cm³. It presents as an irregularly shaped, heterogeneously enhancing mass with a prominent central necrotic or cystic component and ill-defined margins.

2. PROBABLE TUMOR TYPE:

- The imaging characteristics, specifically the irregular, heterogeneous ring enhancement with a central necrotic core and ill-defined margins in a 35-year-old male, are highly concerning for a high-grade glial neoplasm, such as a Glioblastoma Multiforme (GBM) or an Anaplastic Astrocytoma. While GBM is less common at this age, these features strongly suggest an aggressive primary brain tumor.

3. RECOMMENDED FOLLOW-UP:

- Referral to Neurosurgery for consideration of stereotactic biopsy or surgical resection for definitive histopathological diagnosis.
- Comprehensive neurological examination.
- Consider additional advanced MRI sequences (e.g., perfusion MRI, magnetic resonance spectroscopy) for further characterization and surgical planning, if deemed necessary by the treating neurosurgeon.
